

Top Ten States for CO₂ Emission Reductions:

- | | |
|-----------------|--------------------|
| 1. Texas | 6. Kentucky |
| 2. Ohio | 7. Michigan |
| 3. Illinois | 8. California |
| 4. Indiana | 9. Georgia |
| 5. Pennsylvania | 10. Alabama |

Alabama’s Carbon Dioxide Pollution could be Dramatically Reduced with Industrial Energy Efficiency and Combined Heat and Power

Alabama Savings

The industrial sector—including manufacturing, mining, construction and agriculture—consumes well over one-third of electricity generated in Alabama, the state’s single largest energy use (Figure 1). This energy consumption coupled with growing demand creates significant savings and emission reduction opportunities.

By increasing industrial energy efficiency (IEE), including combined heat and power (CHP) and waste heat to power (WHP), Alabama can:

- **Reduce annual carbon dioxide (CO₂) emissions by 5.6-million tons** in 2030;
- **Achieve about 30 percent of Alabama’s emission reductions** called for under the U.S. Environmental Protection Agency’s (EPA) Clean Power Plan (CPP);
- **Save 9.7-million megawatt-hours** of electricity in 2030;
- **Make industrial companies more competitive** by cutting their energy bills; and
- **Save businesses customers \$5.8 billion** in cumulative cost savings (2016-2030) from avoided electricity purchases.

An [Alliance for Industrial Efficiency](#) analysis (using the American Council for an Energy-Efficient Economy’s [SUPR 2](#)¹ calculator) estimates savings in a scenario where each state:

1. The industrial sector ramps up to an annual 1.5% energy savings target by 2030; and
2. The commercial and industrial sectors install a portion of the technical potential for new CHP and WHP.

Figure 1. Share of total energy consumed by end-use sector in Alabama, (2014)²

Table 1. Savings in Alabama from IEE, CHP, and WHP

	Annual CO ₂ savings (short tons)	Annual energy savings (MWh)	Cumulative utility bill savings through 2030 (million 2011\$)
IEE	4,959,862	6,976,763	\$4,131
CHP/WHP	611,000	2,705,000	\$1,661
Total	5,570,862	9,681,763	\$5,792

Alabama ranks 10th in the U.S. for potential CO₂ reductions from IEE and CHP/WHP. An annual reduction of 5.6 short tons of annual CO₂ emissions is equivalent to emissions from nearly 2 coal-fired power plants or 533,664 homes’ energy use for one year.

Top Ten States for CO₂ Emission Reductions:

- | | |
|-----------------|--------------------|
| 1. Texas | 6. Kentucky |
| 2. Ohio | 7. Michigan |
| 3. Illinois | 8. California |
| 4. Indiana | 9. Georgia |
| 5. Pennsylvania | 10. Alabama |

Clean Power Plan

The Clean Power Plan (CPP) establishes customized targets for states to reduce the carbon pollution produced from power plants that reflect each state’s energy mix. In February 2016, the Supreme Court stayed implementation of the CPP pending judicial review. Despite the stay, some states are choosing to continue to work to cut CO₂ emissions from power plants and explore pathways to compliance. Alabama is currently continuing planning.

The CPP requires Alabama to reduce its annual CO₂ emissions by about 18.7 million short tons by 2030. Our analysis shows that industrial energy efficiency and CHP/WHP would result in an annual reduction of 5,570,862 short tons of CO₂ by 2030 – or approximately 30 percent of needed reductions across the state (Figure 2). Thus, IEE and CHP/WHP can play a central role in helping Alabama achieve its compliance targets.²

Market Value of Savings

Under the CPP final rule, industrial hosts can generate revenue by selling credits (emission reduction credits or allowances). As Table 2 shows, the size of the allowance market is huge. Note that the table shows the market value of savings in a single year; investments would generate a value stream that lasts for many years.

Figure 2. Alabama CPP target achievable through IEE and CHP/WHP

Table 2. Estimated allowance market value if IEE and CHP/WHP savings are realized (2030)

Price per unit of trading	Size of Allowance Market (\$ million)
\$10	\$77.45
\$20	\$154.91

Note: We apply the price per trading unit to combined annual energy savings in 2030. 1 MWh = 0.8 short tons of CO₂.
