

Top Ten States for CO₂ Emission Reductions:

- | | |
|-----------------|---------------|
| 1. Texas | 6. Kentucky |
| 2. Ohio | 7. Michigan |
| 3. Illinois | 8. California |
| 4. Indiana | 9. Georgia |
| 5. Pennsylvania | 10. Alabama |

Texas' Carbon Dioxide Pollution could be Dramatically Reduced with Industrial Energy Efficiency and Combined Heat and Power

Texas Savings

The industrial sector—including manufacturing, mining, construction and agriculture—consumes almost one-half of electricity generated in Texas, the state's single largest energy use (Figure 1). This energy consumption coupled with growing demand creates significant savings and emission reduction opportunities.

By increasing industrial energy efficiency (IEE), including combined heat and power (CHP) and waste heat to power (WHP), Texas can:

- **Reduce annual carbon dioxide (CO₂) emissions by 16.4-million tons** in 2030;
- **Achieve about 26 percent of Texas' emission reductions** called for under the U.S. Environmental Protection Agency's (EPA) Clean Power Plan (CPP);
- **Save 37.4-million megawatt-hours** of electricity in 2030;
- **Make industrial companies more competitive** by cutting their energy bills; and
- **Save businesses customers \$23.2 billion** in cumulative cost savings (2016-2030) from avoided electricity purchases.

An [Alliance for Industrial Efficiency](#) analysis (using the American Council for an Energy-Efficient Economy's [SUPR 2](#)¹ calculator) estimates savings in a scenario where each state:

1. The industrial sector ramps up to an annual 1.5% energy savings target by 2030; and
2. The commercial and industrial sectors install a portion of the technical potential for new CHP and WHP.

Figure 1. Share of total energy consumed by end-use sector in Texas, (2014)²

Table 1. Savings in Texas from IEE, CHP, and WHP

	Annual CO ₂ savings (short tons)	Annual energy savings (MWh)	Cumulative utility bill savings through 2030 (million 2011\$)
IEE	12,924,917	20,209,881	\$13,375
CHP/WHP	3,500,000	17,238,000	\$9,800
Total	16,424,917	37,447,881	\$23,175

Texas ranks 1st in the U.S. for potential CO₂ reductions from IEE and CHP/WHP. An annual reduction of 16.4 million short tons of annual CO₂ emissions is equivalent to emissions from more than 4 coal-fired power plants or 1,573,435 homes' energy use for one year.

Top Ten States for CO₂ Emission Reductions:

- | | |
|-----------------|---------------|
| 1. Texas | 6. Kentucky |
| 2. Ohio | 7. Michigan |
| 3. Illinois | 8. California |
| 4. Indiana | 9. Georgia |
| 5. Pennsylvania | 10. Alabama |

Clean Power Plan

The Clean Power Plan (CPP) establishes customized targets for states to reduce the carbon pollution produced from power plants that reflect each state’s energy mix. In February 2016, the Supreme Court stayed implementation of the CPP pending judicial review. Despite the stay, some states are choosing to continue to work to cut CO₂ emissions from power plants and explore pathways to compliance. Although Texas has suspended CPP planning, states will likely need to identify CO₂ emission reduction strategies in the near future.

The CPP requires Texas to reduce its annual CO₂ emissions by about 62.3 million short tons by 2030. Our analysis shows that industrial energy efficiency and CHP/WHP would result in an annual reduction of 16,424,917 short tons of CO₂ by 2030 – or approximately 26 percent of needed reductions across the state (Figure 2). Thus, IEE and CHP/WHP can play a central role in helping Texas achieve its compliance targets.²

Market Value of Savings

Under the CPP final rule, industrial hosts can generate revenue by selling credits (emission reduction credits or allowances). As Table 2 shows, the size of the allowance market is huge. Note that the table shows the market value of savings in a single year; investments would generate a value stream that lasts for many years.

Figure 2. Texas CPP target achievable through IEE and CHP/WHP

Table 2. Estimated allowance market value if IEE and CHP/WHP savings are realized (2030)

Price per unit of trading	Size of Allowance Market (\$ million)
\$10	\$299.58
\$20	\$599.17

Note: We apply the price per trading unit to combined annual energy savings in 2030. 1 MWh = 0.8 short tons of CO₂.
